This assignment added to my understanding of nesting statements and variable scope.

If I had more time on this exercise I would figure out how to allow users to click on individual words to move them and I would play with restricting the random color generator to develop a color scheme.

What I got right away was string manipulation.

I think the reason I couldn't get the paragraphs clickable was that they do not exist when the document is created, so the onclick event needs to be ran for them once they are created. However, creating an onclick within the for loop was too difficult for me to figure out. It either did not work or stopped the for loop from creating more than one paragraph, or sometimes both. Whatever restriction or flaw preventing from allowing this portion of the script to run properly is new to me, as well is JSLint telling me `i` is not defined upon it being defined in a variable initiation in a for loop. Attempting to access elements by tag within a parent id is also new to me.

The most challenging but rewarding part of the project was getting the record array to generate paragraphs in the html.

This has me wanting to figure out how to use `GetElementsByClass(names)` because when I tried using it told me it was undefined.

The CSS and HTML strongly related to courses I have taken in the past in Web Design. The datatypes I rememehr similarly from my brief experience with PHP.

`ChildNodes` and `GetElementsByClass` haven't been covered in the book thus far, however I wasn't able to get it to work
